## Abstract

This study identifies the driving forces that contribute to the probabilities of incidence of out-of-pocket (OOP) expenditures by households in Turkey. Factors affecting the probability of OOP expenditures on medical products/devices/supplies (MP), outpatient services (OTS), and inpatient services (ITS) are examined using the Household Budget Survey (HBS) data gathered by the Turkish Statistical Institute in 2018. The study applies the multivariate probit model to account for the possible relationship across the three categories of healthcare expenditure. The incidence of OOP spending varied with 48.9% of the households reporting OOP expenditure on MP, 22.4% on OTS, and 25.4% on ITS. The largest probability changes were associated with the household income, household type and size, age category, and having private health insurance. Gender and marital status also influenced expenditures on some categories. Lifestyle choices had small and mixed effects, with smoking and alcohol consumption lowering the probability of OOP spending. From a policy standpoint, households with the lowest incomes, large households and those where the household head was unemployed or had a condition preventing working seemed to report the OOP expenditures less frequently and may have chosen not to received healthcare services leading to the need for more healthcare services later.

**Keywords:** Out-of-pocket expenditures, outpatient services, inpatient services, multivariate probit, Household Budget Survey.

## 1. Introduction

The acquisition of healthcare services commonly requires payment<sup>1</sup>. Both public and private schemes provide healthcare financing. The purpose of healthcare financing is to ensure access to private and public health services by providing the right financial incentives<sup>2</sup>. Public financing methods include taxes and social insurance contributions, and the mechanism varies

1  
2  
3 across countries. Private financing includes purchase of health insurance and out-of-pocket  
4 (OOP) payments <sup>3</sup>.

5  
6  
7 A well-planned health care system financing protects society against financial risks. The  
8 costs of healthcare services are increasing rapidly due to the growing elderly population,  
9 chronic diseases, and technically more complicated costly treatments <sup>4</sup>. The way health systems  
10 are designed, managed, and financed affects the lives and livelihoods of individuals <sup>2</sup>. The threat  
11 of out-of-pocket (OOP) payments to the household living standard is increasingly considered  
12 in health financing <sup>4</sup>. The out-of-pocket payment is the dominant form of financing health  
13 services in developing countries <sup>5</sup>. In those countries, including the Middle East and North  
14 Africa (MENA), the majority of the healthcare service expenses are OOP expenditures of  
15 patients or their families <sup>6; 7, 8</sup>. Providing financial protection against excessive OOP is an  
16 important policy for the health system. In the absence of such a policy, a household may face a  
17 high burden of spending on treatment and medical bills and allocate time to caring for of family  
18 members. OOP expenditures are the issue that policymakers focus because of their  
19 consequences for the patients, households, and society <sup>9</sup>.

20  
21  
22 In the 21st century, the OOP expenses constitute an important obstacle in access to  
23 health services <sup>10</sup>. Access to health services depends on the economic status of individuals or  
24 households. If the health service cost is not affordable, it prevents receiving the needed care <sup>5</sup>.  
25 Borrowing money, selling assets, or using other funds to receive healthcare services are some  
26 approaches used by households. Households may choose least-cost care or completely forgo  
27 the healthcare services they need <sup>11</sup>. Therefore, the OOP payments are considered unfair <sup>12</sup>. One  
28 of the main purposes of both national and international health policy is to replace OOP  
29 payments with alternative forms of financing. In this context, knowing the predictors of the  
30 probability and levels of OOP expenditure is essential to assure that no one is left without  
31 healthcare services and maintain universal healthcare coverage <sup>13</sup>. The role of socioeconomic,

60

1  
2  
3 lifestyle, environmental, and geographic factors, among others has been documented to  
4  
5 determine health and health-seeking behavior <sup>2, 14</sup>.  
6

7  
8 OOP spending on health care is the primary source of financing next to public health  
9  
10 expenditures in terms of the amount and percentage of total expenditures in most countries <sup>15</sup>.  
11  
12 OOP expenditures, referring to the payments made by households to receive healthcare  
13  
14 services, have been increasing in the last two decades in Turkey <sup>16</sup>. OOP payments for  
15  
16 treatment, pharmaceuticals, and other services and supplies reached 28.655 billion TL,  
17  
18 increasing by of 19.4% in 2018 alone. The share of OOP payments in total health expenditures  
19  
20 was 17.3% in Turkish households in 2018 <sup>17</sup>. Most studies analyzing the determinants of OOP  
21  
22 expenditures in developed and developing countries have focused on spending levels or  
23  
24 separate probabilities for outpatient and inpatient services <sup>13, 18</sup>. However, the likelihood of  
25  
26 household spending on medical products, outpatient and inpatient treatment, and the possibility  
27  
28 of the simultaneous occurrence of those services has been ignored. The monthly OOP spending  
29  
30 on, for example medical products, undoubtedly affects other healthcare services. Therefore,  
31  
32 studies that neglected the relationship between the spending amount or probabilities of incurring  
33  
34 such expenses can compromise important statistical results due to the limitations of the  
35  
36 estimation method.  
37  
38  
39  
40  
41

42  
43 This study recognizes that the health care involves a number of services and supplies  
44  
45 and distinguishes the OOP spending on three categories, the expenditures on medical products,  
46  
47 supplies, and materials (MP), outpatient treatment services (OTS), and inpatient treatment  
48  
49 services (ITS). The methodological approach considers the realities faced by the patient and his  
50  
51 household by adopting the simultaneous modeling framework that allows for the relationship  
52  
53 across the three categories of OOP expenditures. The application of the multivariate probit  
54  
55 regression (MPR) analysis accommodate the likelihood of the OOP expenditures in one  
56  
57 category being influenced by those involving another category of health care service. The  
58  
59  
60

1  
2  
3 approach allows the identification of factors influencing the expenditure in each category from  
4  
5 the large pool of socio-demographic and economic characteristics of the household and the  
6  
7 household head providing superior insights applicable in the formation of healthcare policies.  
8  
9 The practical recommendations for policy makers are generated from the calculation of the  
10  
11 marginal effects of regressors derived from the joint probabilities. The quantified measures, i.e.,  
12  
13 the probability changes that expenditures in a specific category took place, are a meaningful  
14  
15 guide for health practitioners and decision-makers in redesigning health expenditures and their  
16  
17 fair redistribution across the country.  
18  
19

## 20 21 **2. Literature Review**

22  
23 The amount of household OOP expenditures differs depending on the complexity and quality  
24  
25 of healthcare services. It is believed that differences in demographic and socio-economic  
26  
27 household features are the most important factors determining OOP spending<sup>4, 5, 19, 20</sup>. OOP  
28  
29 expenditures are of particular concern to both households and policy-makers in developing  
30  
31 countries such as Turkey and countries with a similar level of development. OOP spending  
32  
33 affects the inclination to use healthcare services, ultimately affecting the individual health  
34  
35 status. Decision-makers need to know the factors that influence households to incur such  
36  
37 expenses.  
38  
39

40  
41 Household OOP expenditures for healthcare services account for 23% of total global  
42  
43 health expenditures and 45% of health expenditures in developing countries<sup>21</sup>. The large OOP  
44  
45 spending is a burden for poor households when it restricts other basic household needs  
46  
47 contributing, for example, to malnutrition because of the obligation to pay for treatment. As a  
48  
49 result OOP expenditures are an important social problem and of great concern for policymakers  
50  
51 due to the consequences for sick family members, households, and society<sup>9, 22</sup>. Household OOP  
52  
53 expenditures are the most important form of financing health services in many developing  
54  
55 countries. Information about household health expenditures is essential for creating an effective  
56  
57  
58  
59  
60

1  
2  
3 healthcare system financing policy for any country<sup>4,23</sup>. For this reason, it is essential to identify  
4 the key factors that influence OOP expenditures in any of the three categories and possibly  
5 differentiate the probability changes that a household incurs such expenditures<sup>19, 24, 25</sup>.  
6  
7  
8  
9

10 The literature on the subject identified demographic, socio-economic, and location  
11 factors as relevant to OOP spending. Among the demographic characteristics are those  
12 characterizing the household head, such as gender<sup>5, 26, 27</sup>, age<sup>28-30</sup>, and marital status<sup>31, 32</sup>. Also,  
13 the household size<sup>33-35</sup> and composition indicated by the presence of children and elderly<sup>5, 36</sup>,

54  
55  
56  
57  
58  
59  
60  
39 have been identified as important determinants of OOP spending. Furthermore, household  
income<sup>4, 19, 25, 40</sup>, employment status<sup>24, 41</sup>, insurance status<sup>16, 42, 43</sup>, and occupation<sup>20, 29</sup> also  
have affected OOP expenditures. The place of residence has been reported to affect the OOP  
expenditures and should be taken into consideration in policy formulation<sup>25, 44</sup>. Additionally,  
OOP spending has been influenced by factors such as the nature of the disease<sup>38, 45-47</sup>, type of  
healthcare facility visited<sup>24</sup>, and affinity to service providers<sup>41</sup>.

40 The study of adult and elderly populations in Tanzania indicated that obesity increases  
41 OOP expenditure for adults<sup>29</sup>. In a study conducted on the determinants of OOP expenditure in  
42 Sri Lanka,<sup>30</sup> found that proximity of state hospitals, number of hospital beds, and presence of  
43 dentists in state hospitals reduce the burden of OOP expenditures. In a study conducted in  
44 Pakistan, non-food household expenditures were found to be the most important determinant  
45 of OOP spending<sup>5</sup>. In a study conducted on the elderly living in rural areas in Odisha, India,  
46 the savings or bank balance, mobility status, hearing status, smoking, and multiple morbidities  
47 were found to be important factors associated with OOP expenditures<sup>48</sup>. Likewise, diabetes,  
48 tuberculosis, malaria, respiratory disorders, gastrointestinal diseases, dementia, depression, and  
49 disability were found to be associated with higher OOP spending of the elderly living in rural  
50  
51

1  
2  
3 areas in India as compared to those not afflicted by such diseases <sup>49</sup>. A study of a psychiatric  
4 clinic in Turkey revealed that the patients diagnosed with schizophrenia and other psychotic  
5 disorders paid more for their treatment than other patients <sup>16</sup>.  
6  
7  
8  
9

10 Overall, numerous studies in lesser developed countries confirmed the association of  
11 demographic and socio-economic characteristics and OOP expenditures. Household location  
12 and nature of the affliction also influenced OOP spending and are worthwhile considerations in  
13 the empirical examination quantifying the probability of OOP spending on the three categories  
14 of healthcare services. The current study uses nationally representative data in identifying the  
15 statistically significant factors determining household OOP expenditures for three service  
16 categories (MP, OPS, and IPS) in Turkey.

### 26 **3. Data and Methods**

#### 27 **3.1. Household Budget Survey**

28 The study applies data from the Household Budget Survey (HBS) conducted in 2018 by the  
29 Turkish Statistical Institute (TSI). The survey sample is representative of the overall society.  
30 The HBS provides information about socioeconomic characteristics, standard of living, and  
31 consumption of households. All settlements within the borders of the Republic of Turkey were  
32 included in the HBS geographical scope. Also, all members present in every household were  
33 included, but those qualified as institutionalized persons and the nomadic population were  
34 omitted. The sample was determined by the stratified two-stage cluster sampling method <sup>50</sup>.  
35 Approximately one thousand families with the same socio-demographic characteristics were  
36 replaced each month by the TSI in order to eliminate the influence of seasonal effects.  
37

41  
42  
43  
44  
45  
46  
47  
48  
49

#### 50 **3.2. Choice of estimation approach**

51 The study focuses on quantifying factors associated with OOP expenditures on the three distinct  
52 categories of healthcare services. Classification of the services is based on the discernable  
53 character of the services such as medication or outpatient treatment, but the study recognizes  
54  
55  
56  
57  
58  
59  
60

that household use of services implies a simultaneous or nearly simultaneous incidence of their purchase. The multivariate probit regression (MPR) technique is preferred when dependent variables are related to each other and has been selected for the estimation. When some of the dependent variables are interrelated through the same set of explanatory variables, the MPR results are more robust than binary logit or probit results obtained using a separate equation for each dependent variable<sup>51</sup> or one of the categories of healthcare services. The general specification for the trivariate probit regression is<sup>52</sup>:

$$\begin{aligned}
 y_{im}^* &= x_{im}'\beta_m + \varepsilon_{im} \\
 y_{im} &= 1 \text{ if } y_{im}^* > 0 \text{ and } 0 \text{ otherwise for } i=1, \dots, N \text{ and } m=1, 2, 3. \\
 E[\varepsilon_m | x_m] &= 0, \text{Var}[\varepsilon_m | x_m] = 1, \text{Cov}[\varepsilon_j \varepsilon_m | x_m] = \rho_{jm} \text{ and } (\varepsilon_1, \varepsilon_2, \varepsilon_3) : N[0, R]
 \end{aligned}$$

(1)

where  $y_{im}^*$  is a latent dependent variable for each  $m$ , while  $y$  is its observed counterpart. A set of independent variables is  $x$  and assumed to be the same in each equation,  $\beta$  is a set of the associated regression coefficients to be estimated, and  $\varepsilon_m$  is an error term for each equation.  $R$  is the variance-covariance matrix with values of 1 on the leading diagonal and correlations  $\rho_{jm} = \rho_{mj}$  as off-diagonal elements. Log-likelihood function for a sample of  $N$  independent households:

$$\log -L = \sum_i \log \Phi_3(\mu_i; R),$$

where  $\Phi_3(\mu_i; R)$  is standard trivariate normal cumulative distribution function (CDF), where  $K_{im} = 2y_{im} - 1$  for each  $i, m=1, 2, 3$ . If the remaining dependent variables (say,  $y_2$  and  $y_3$ ) are equal 1, then the conditional expectation of the other dependent variable (say,  $y_1$ ) is given:

$$E[y_1 | y_2 = 1 \text{ and } y_3 = 1] = \frac{\text{Prob}(y_1 = 1, \dots, y_3 = 1)}{\text{Prob}(y_2 = 1, y_3 = 1)},$$

while the denominator is bivariate CDF. The remaining two conditional expectations can be

1  
2  
3 constructed likewise. The effect of any regressor on the conditional probability is calculated by  
4  
5 differentiating such conditional probability with respect to the corresponding regressor. If  $\Sigma$  is  
6  
7 the asymptotic covariance matrix for the coefficient estimates, then the variance of the predictor  
8  
9 of marginal effects (ME) is obtained as the mean square deviation of 100 random draws from  
10  
11 the distribution of the underlying slope parameters <sup>53</sup>.

### 14 **3.3. Outcome variables and covariates**

16  
17 The dependent variables in the current study include OPP expenditures for three healthcare  
18  
19 service categories: medical products/supplies/materials (MP), outpatient treatment service  
20  
21 (OTS), and inpatient treatment service (ITS). Each dependent variable is binary, i.e., coded as  
22  
23 “1” if the household incurs any OPP expenditures for a specific category, otherwise coded “0”.

24  
25  
26 The MP category includes the probability of spending on pharmaceutical products,  
27  
28 pregnancy tests, contraceptive mechanical devices, medical products not classified elsewhere,  
29  
30 corrective eyeglasses and contact lenses, hearing aids, repair of therapeutic instruments and  
31  
32 equipment, and other therapeutic instruments and equipment. The second category, OTS,  
33  
34 considers the likelihood of household OOP spending on general practitioners, specialist  
35  
36 physicians, dental services, medical analysis laboratory and x-rays, spa services, corrective  
37  
38 gymnastic treatment, ambulance services, leasing of therapeutic equipment, and other  
39  
40 paramedical services. Finally, the ITS category, considers expenditures on hospital stays.

41  
42  
43  
44 The explanatory variable selection stems whenever possible from the results of studies  
45  
46 reviewed earlier as well as variables considered relevant in predicting the likelihoods of the  
47  
48 household OOP expenditures in each category. Demographic and socioeconomic factors,  
49  
50 factors related to household lifestyle choices, and housing were included among the explanatory  
51  
52 variables (Table 1). It is noted that because the relationship between the probability of OOP  
53  
54 expenditures and risk factors has been widely discussed in the literature <sup>8, 24, 25</sup>, it would have  
55  
56 been redundant to discuss it here.  
57  
58  
59  
60

## 4. Results and Discussion

### 4.1. Summary statistics

The sample based on the HBS and used in the current study shows that 48.9%, 22.4%, and 25.4% of households, respectively, reported the OPP expenditures for MP, OTS, and ITS category. Interestingly, the spending incidence on MP category is roughly twice that of the other two service categories accounting for patient treatment. The spending frequency on the OTS and ITS categories were similar.

Table 1 shows the frequency and percentage of demographic, socioeconomic, lifestyle, and housing factors in the HBS sample.

To reduce the risk of potential estimation problems, Table 1 shows the VIF values calculated for each characteristic intended to be used in the estimation of equations modeling the likelihood of incidence of OOP expenditures in the three categories. Variables with a VIF value of 5 but less than 10 are considered to indicate a moderate degree of multicollinearity, while those with a VIF value of 10 and higher are to show a high degree of multicollinearity<sup>54</sup>. None of the variables included in the modeling has a VIF value of 5 or higher (Table 1) showing that the moderate or severe multicollinearity is absent between the selected regressors.

### 4.2. The MPR estimation results

Table 2 shows parameter estimates of the maximum likelihood function, along with their statistics and marginal effects (ME) for each likelihood of the household OPP expenditures in the three categories, MP, OTS, and ITS. The choice of the estimation approach using the multivariate probit model is confirmed by the statistically significant correlation coefficients. The correlation coefficients indicate, a positive relationship between the dependent variables and justifies the estimation of a single model. The null hypothesis that the correlation coefficients were simultaneously zero was rejected (Likelihood Ratio (LL) test value =2737.48 with 3 (df) and  $p < 0.001$ ). Also, the LL test revealed that all explanatory variables used in the

1  
2  
3 three-equation system are simultaneously nonzero, and the regressors jointly explain each  
4 probability decision ( $LL = 972.67$ ,  $df = 147$ , and  $p < 0.001$ ). From policy standpoint, that result  
5 establishes that there is interaction across the three equations and that the incidence of spending  
6 on one of the three categories can be associated with expenditures on the remaining two  
7 categories.  
8  
9

10  
11  
12  
13  
14  
15 Most of the demographic and socio-economic characteristics affect the probability of  
16 the OOP health expenditures in each of the three categories (Table 2). Specific effects have  
17 distinct magnitude and sign in each category of the OOP expenditure. The estimated  
18 coefficients lack practical interpretation until they are converted into measures of probability  
19 change in the incidence of the OOP expenditure on a given category of health care services.  
20 The individual marginal effects (ME) of explanatory variables on OOP health expenditure are  
21 interpreted assuming all other variables are constant. The MEs in Table 2 are discussed in detail  
22 in the next section.

### 32 33 **4.3. Discussion**

34  
35 Male-headed households are less likely to incur OOP expenditures for all categories of  
36 healthcare services. This result coincides with earlier findings that women have higher health  
37 expenditures<sup>5, 27, 29</sup>. Women consume additional healthcare services due to pregnancy. Women  
38 also tend to spend more on all three categories than men because of concerns about the health  
39 of family members, including children<sup>27</sup>. Considering household income, households in the  
40 lowest quartile are covered by the government general health insurance, but additional  
41 programs could protect that group from OOP expenditures.  
42  
43  
44  
45  
46  
47  
48  
49  
50

51  
52 The educational attainment level may affect the OOP expenditure decision in a specific  
53 category because education shapes health-related behavior. In this study, the probability of  
54 more education increasing OOP expenditures on the MP, OTS, and ITS categories is low where  
55 the household head reported having high school or university education as compared to those  
56  
57  
58  
59  
60

1  
2  
3 without a school diploma. However, the effect is statistically significant only in the case of MP  
4 expenditures. The results differ from earlier findings in other countries<sup>5, 30, 38, 39, 55</sup> because OTS  
5 and ITS expenses can be covered by the family health insurance. The positive link between  
6 education and OOP health expenditures was common in previous studies<sup>5, 30, 38, 39, 55</sup>. On the  
7 other hand, one could expect that the higher the education level, the lower the probability of  
8 spending by category, given that those with more education make healthier lifestyle choices<sup>56</sup>,  
9 and have more knowledge to better cope with illnesses or injuries<sup>13</sup>.

10  
11  
12 Household heads in four age categories (ranging from 25 years to 64 years of age) were  
13 less likely to make OOP expenditures for both the MP and OTS categories. A similar tendency  
14 is shown for OOP spending on ITS services for those in age groups 45-54 and 55-64 as  
15 compared to households headed by those 65 years old or older. The probability of OOP  
16 spending decreases as the household head age falls between 45-54 years of age, and the  
17 probability decrease is lowest for those 25-34 years of age as compared to those 65 years of age  
18 and older. Among the three categories, health expenditure for MP has the highest probability,  
19 while spending on the ITS category is the lowest. It is plausible that the ITS expenditures are  
20 covered in full or in part by the family health insurance. However, a fully-fledged financial  
21 protection mechanism should be developed and implemented to limit the OOP expenditure for  
22 low-income families. Families who save on OOP spending may have an opportunity to improve  
23 nutrition once they are able to redirect purchases due to improved coverage by aid programs.  
24 Providing households with assistance to cover healthcare expenses early could mean lower  
25 healthcare costs borne by the government in the future.

26  
27  
28 The household head's age is one of the main demographic characteristics. The age  
29 variable may represent age-related healthcare needs. The increased comorbidity and mortality  
30 rates due to chronic diseases are mostly observed in the elderly population<sup>57</sup>. Moreover, large  
31  
32  
33  
34  
35

48  
49  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 healthcare expenditures are attributed to declining health as people age, increased injury  
4  
5 frequency in later stages of life, and chronic diseases associated with aging <sup>35</sup>.  
6  
7

8 Assuming that age may affect the use of healthcare services differently, its effect may  
9  
10 not have a linear relationship with the likelihood of incurring health expenditures. The non-  
11  
12 linearity could also result from the access and use of healthcare services related to  
13  
14 socioeconomic conditions in later stages of life <sup>58</sup>. For example, the low-income elderly tend to  
15  
16 be in poorer health but use less health care services than those with more income, irrespective  
17  
18 of age <sup>59</sup>. Earlier studies reported that as the age of the household head increases to a certain  
19  
20 level, the likelihood of making OOP expenditures decreases. Households with a household head  
21  
22 65-years-old and older frequently make OOP expenditures. An aging population is also the  
23  
24 main driving force of increasing healthcare expenditures. Elderly individuals are a vulnerable  
25  
26 community that significantly increases healthcare expenditures <sup>30, 60</sup>. The current study results  
27  
28 support previous findings that healthcare expenditures increase with advancing age, especially  
29  
30 after the age of 65 <sup>19, 29</sup>.  
31  
32  
33  
34

35 Marital status affected the probabilities of OOP spending. In this study, never-married  
36  
37 household heads are less likely to report OOP expenditures on all healthcare service categories  
38  
39 than those married. In general, married household heads are likely to have higher OOP  
40  
41 expenditures due to healthcare needs for themselves, spouses, and children than household  
42  
43 heads that are not married <sup>27</sup>. Also, insurance that provides access to healthcare is obligatory  
44  
45 for those who do not have sufficient financial resources <sup>61</sup>. The OOP spending varied depending  
46  
47 on whether the household had health insurance. As expected, households without health  
48  
49 insurance have high OOP expenditures. However, there is some evidence that households that  
50  
51 are covered by health insurance also have high OOP expenditures <sup>16, 19, 24, 42</sup>. The current study  
52  
53 confirms that households with compulsory and private health insurance have higher OOP  
54  
55 spending on all three categories of services as compared to households lacking insurance.  
56  
57  
58  
59  
60

1  
2  
3 However, as expected, the probability values in the case of private healthcare expenditures are  
4  
5 higher than those when a household has mandatory health coverage. The likely reason behind  
6  
7 this finding is that households with a large number of uninsured individuals tend to use fewer  
8  
9 healthcare services due to financial constraints and thus are less likely to spend OOP on the  
10  
11 three categories of services. Such families may be less likely to spend OOP on public and  
12  
13 private healthcare providers that adopt integrated management and cost-sharing programs. In  
14  
15 contrast, households with more insured individuals may be less price-conscious about health  
16  
17 expenditures and seek healthcare services <sup>19</sup>.

21  
22 The current study confirms the importance of occupation for the incidence of OOP  
23  
24 expenditures. Households where the household head was a professional or an artist are more  
25  
26 likely to spend on the MP category, while household heads with white collar jobs and those  
27  
28 with jobs for unskilled laborers are unlikely to spend on OTS. Studies showing that households  
29  
30 headed by an employed worker had a higher likelihood of making OOP expenditures <sup>24</sup> but  
31  
32 that unemployment is also an important determinant of OOP expenditures <sup>41</sup> is supported by  
33  
34 the current study findings. On the other hand, households where the head was disabled are more  
35  
36 likely to have OOP expenditures. The finding is consistent with previous reports <sup>45, 47, 62</sup>.  
37  
38 Individuals with chronic diseases or conditions tend to need regular checkups and treatment  
39  
40 more frequently than other household members <sup>46</sup>. Considering the probability of such families  
41  
42 being poor and the incidence of some poorer households postponing a treatment because they  
43  
44 cannot afford OOP expenses, modifying the financial protection programs by providing the  
45  
46 needed care and equitable distribution of healthcare services throughout the country would be  
47  
48 more efficient in assuring good health of the population.

53  
54 Previous studies established that income is one of the main triggers of OOP  
55  
56 expenditures. In the current study, compared to families with the lowest income (e.g. lowest  
57  
58 quartile), all higher income quartiles have higher probabilities of OOP expenditures on the MP  
59  
60

1  
2  
3 and OTS categories. In particular, as household income increases, the probability of incurring  
4 MP expenditures increases by about 14% for the 2<sup>nd</sup> and 3<sup>rd</sup> quartile and more than 16% for the  
5 highest income group (Table 2). The probabilities of having OTS expenditures are larger and  
6 amount to 14% for the 2<sup>nd</sup> quartile, 18% for the 3<sup>rd</sup> quartile and a whopping 26% for households  
7 with the highest incomes. The results suggest that the use of OTS is strongly influenced by  
8 household income, and, presumably, implies better health conditions of household members in  
9 the higher income groups as compared to households with less income. It appears that OOP  
10 spending on ITS services is more equal since the calculated probabilities of having OOP costs  
11 for the 2<sup>nd</sup> and 3<sup>rd</sup> income quartile are small (Table 2), and even negative for the highest income  
12 group. The results likely reflect the existing government healthcare programs and possibly  
13 having private insurance in the case of households with highest incomes. Those findings echo  
14 previous results <sup>4, 25, 40</sup>. As incomes rise, the likelihood of spending on all categories increases,  
15 reflecting the tendency to use more healthcare services, more expensive or specialized treatment  
16 services <sup>63</sup>.

59  
60

Household type has a varying effect on the probability of OOP expenditures in any of the three categories of services (Table 2). The probability of OOP spending on the MP category decreases for households of singles by nearly 44% and for a single parent raising children by almost 26%. It also decreases in households of childless couples, but only by about 10%. (Table 2). In the case of the OOP spending on OTS, the probability of such spending decreases only in the case of a single parent raising children by about 13%. It is possibly associated with the special government programs providing health care for children. Households of nuclear families with other persons (possibly multigenerational households), the probability of OOP expenditures on OTS services increases by more than 12% (Table 2). This is also the only household type associated with an increasing probability of having OOP expenses on the ITS category, although the increase is only about 5%. Households classified as other types, except

1  
2  
3 for childless couples, have a lower probability of OOP spending on the ITS category of 11% or  
4  
5 less. An increasing household size (a continuous variable in Table 2) lowered the probability  
6  
7 of OOP expenditures but by a decreasing amount across the three categories: by almost 10% in  
8  
9 the case of MP, nearly 6% on OTS, and under 4% in the case of ITS. Overall, results coincide  
10  
11 with the findings of previous studies linking household size to OOP spending <sup>24, 35, 56</sup>.

12  
13  
14 Having private health insurance increases the probability of OOP spending on all  
15  
16 categories (Table 2). The magnitude of the probability is largest in the case of MP services,  
17  
18 19%, about 14% in the case of OOP spending on OTS, and considerably smaller but still  
19  
20 positive (more than 3%) in the case of ITS services. Because private health insurance is  
21  
22 voluntary it is believed to be more prevalent among households with high incomes. The demand  
23  
24 for private insurance is affected by various economic, social, and demographic factors <sup>64</sup>.  
25  
26 Additionally, high Gross Domestic Product (GDP) per capita, health expenditures, and level of  
27  
28 education are the strongest determinants of the use of private insurance <sup>65</sup>.

29  
30  
31  
32  
33 Having a credit card increases the probability of OOP spending as compared to  
34  
35 households not using that method of payment, but the increases range from small to marginal  
36  
37 (Table 2). The probabilities associated with the MP and OTS categories have more pronounced  
38  
39 effects because payments for those services are, as expected, easier with a credit card.

40  
41  
42 To deal with the cost of illness, households either use their savings and income or rely  
43  
44 on constrained means of financing such as the depletion of household assets, loans, and family  
45  
46 and friend support <sup>66</sup>. The main reason for making fewer health service purchases is a lack of  
47  
48 money or savings <sup>48</sup>. However, one of the interesting results of the current study is that  
49  
50 households with savings have a lower probability of OOP spending on the MP (nearly 6%) and  
51  
52 OTS (almost 7%) categories than those without savings.

53  
54  
55 Variables associated with lifestyle choices have a mixed effect on OOP expenditures on  
56  
57 the three categories of services. The probability of having OOP expenditures are smaller in  
58  
59  
60

1  
2  
3 households using tobacco (about 8%) and alcohol (about 7%) on MP services and on IPS in the  
4  
5 case of tobacco use (almost 3%). The latter result could be associated with the government  
6  
7 healthcare program covering ITS when some tobacco users may require hospital stays. Families  
8  
9 that report eating out had a markedly higher probability of having OOP expenditures on the MP  
10  
11 category (more than 17%) and on ITS services (nearly 7%). Households frequenting cinemas  
12  
13 or sports events had a slightly smaller probability, about 5%, of OOP expenditures on ITS  
14  
15 services (Table 2), while playing games of chance increased the probability of OOP  
16  
17 expenditures on the MP category by nearly 6%. If visiting coffee houses, cafes, or lounges  
18  
19 was a part of a household lifestyle, the probability of OOP expenditures on the MP and ITS  
20  
21 categories increased by about 5% and 3.5%, respectively. Shopping at open-air markets or  
22  
23 online tend to increase OOP expenditure probability on all three health service categories,  
24  
25 except for the spending on the ITS category in the case of online purchases (Table 2). It appears  
26  
27 that lifestyle choices matter in the incidence of OOP payments, but the effects measured as the  
28  
29 probability changes on any of the three categories varied in their direction and magnitude. It is  
30  
31 likely that dynamically changing lifestyles could lead to more changes in OOP expenditure and  
32  
33 may have to be tracked more accurately.  
34  
35  
36  
37  
38

## 39 **5. Conclusion**

40  
41  
42 The accessibility of healthcare services, expanding their use, and reducing the potentially  
43  
44 catastrophic effect of healthcare expenses on households are of paramount importance to  
45  
46 governments. In Turkey, those overarching measures, including fair and efficient distribution  
47  
48 of healthcare services are a major focus of government programs, especially the reduction of  
49  
50 risk of impoverishing a household as a result of OOP expenditures.  
51  
52

53  
54 The investigation of factors influencing the probability of OOP expenditures on three  
55  
56 categories of healthcare services involves a nation-wide sample of households from the HBS in  
57  
58 Turkey. The approach recognizes the possible relationships across the three categories of  
59  
60

1  
2  
3 services, i.e., MP, OTS and IPS, and applies the multivariate probit (MP) modeling. The  
4 suitability of multivariate probit model is confirmed by statistical testing. The examination of  
5 healthcare expenditure categories as a system of three equations does not compromise key  
6 statistical properties such as efficiency of parameter estimates. The calculated correlation  
7 coefficients in the MP model are positive and statistically significant suggesting a decrease in  
8 the probability of OOP spending in one category when the value of any explanatory variable  
9 increases the probability of OOP expenditure on another healthcare service category.

10  
11  
12  
13  
14  
15  
16  
17  
18  
19 The key practical findings have to do with the marginal effects that measure changes in  
20 probability of OOP expenditures on the specific healthcare service category in response to a  
21 change in a specific explanatory variable. Results show that particularly large changes in the  
22 probability of OOP spending are associated with gender, several age categories, and marital  
23 status in the case of spending on MP services. Overall, the probability changes were particularly  
24 large in OOP spending on MP services and were increasing for some household types, all but  
25 the lowest income quartile, and having private insurance. Similar in direction (increasing or  
26 decreasing) but somewhat lower in magnitude were the changes in the probability of OOP  
27 expenditures on the OTS category. As in the case of the MP category, the spending on the OTS  
28 category was particularly strongly affected by age, marital status, all income categories except  
29 for the lowest quartile, selected household types, and having private insurance. The calculated  
30 probability changes associated with OOP spending on the IPS category followed a pattern  
31 similar to the other healthcare service categories but the effects were markedly smaller. The  
32 latter result is likely associated with the existing government healthcare programs and a system  
33 of government-managed hospitals.

34  
35  
36  
37  
38  
39  
40  
41  
42  
43  
44  
45  
46  
47  
48  
49  
50  
51  
52  
53  
54 For policymakers, the study results provide important insights into increasing the  
55 effectiveness of healthcare policies and the determination of a fair financial burden of  
56 expenditures on healthcare. The likelihood of OOP expenditures by households in the lowest  
57  
58  
59  
60

1  
2  
3 income quartile is low but still present. It is plausible that low-income households chose not to  
4 receive any healthcare services due to the lack of funds. For this reason, at-risk, low-income  
5 households require policy makers to consider suitable mechanisms for assuring healthcare  
6 service accessibility. The government of Turkey covers certain healthcare expenditures for all  
7 households, but some households purchase private health insurance to cover others. Therefore,  
8 the possibility of healthcare expenditures having a catastrophic effect on a household varies and  
9 ear of such costs may affect behavior in seeking needed healthcare services.

10  
11  
12  
13  
14  
15  
16  
17  
18  
19 Households headed by someone unemployed have a lower probability of being faced  
20 with OOP expenditures, possibly indicating that the lack of income may delay seeking medical  
21 care. Improving healthcare access for the unemployed will also reduce the unregistered  
22 unemployment. Households indicating a member with a condition preventing work are more  
23 likely to incur OOP expenditures. It appears that policies addressing specific needs of citizens  
24 with work-preventing conditions by improving their access to healthcare services will reduce  
25 household OOP expenditures. The disabled may have special needs including equipment, non-  
26 prescription medication, and physical therapy services not commonly sought by other types of  
27 households and having access to those services will improve their life quality and help integrate  
28 them into society at large.

29  
30  
31  
32  
33  
34  
35  
36  
37  
38  
39  
40  
41  
42 Finally, large households seem to have a lower probability of OOP spending on any of  
43 the three categories of healthcare services. It is not clear whether the lower probability is linked  
44 to the demographic composition of the household. For example, households with many young  
45 children may benefit from special government programs already addressing their needs. A  
46 future study may explore that aspect together with the presence of elderly in a household.
